

How does a laser diode change color

Overview

Laser diodes span a wide range of emission wavelengths, from infrared to visible blue and violet, depending on the semiconductor alloy used (such as ZnSe or GaN compounds). The laser diode chip is the small black chip at the front; a photodiode at the back is used to control output power. The anode connection on the right has been accidentally broken by the case cut. Once enough photons build up (a threshold called “population inversion”), the light escaping from one partially reflective end is coherent: a tight, single-color beam rather than a broad spray of mixed wavelengths. The minimum current needed to reach this point is called the threshold current, and. There are different properties of laser diodes some of which are discussed briefly here: Monochromatic means composed of a single color. This feature is applied in fields such as fiber optics. Laser diodes are monochromatic because it emits light of one color of a particular wavelength.
