

Insertion Loss of Pigtail Connectors

Overview

Insertion loss, also known as attenuation, is the loss of optical power that occurs when light passes through a fiber optic connector. It is caused by factors such as misalignment, air gaps, and imperfections in the connector components. It is the difference between the input power and the output power of the link, expressed in decibels (dB). The insertion loss is caused by various factors, such as the misalignment of. In the test report for a fiber cable, you may often see some data related to fiber insertion loss (IL) and return loss (RL), but do you know what insertion loss and return loss actually mean?

How do the values of IL and RL impact the quality of the fiber cable?

Are higher values better, or lower. Fiber optic connectors main function is designed to terminate the ends of fiber optic cables so they can be interconnected. Every fiber connection has two most important values after termination and interconnection - Insertion Loss (IL) and Reflection or Return Loss (RL). Typical applications include data centers, Broadband CATV, Passive Optical Network PON, WDM or DWDM multiplexing, FTTh, and voice services in ATM and SONET.
