

Is the beam splitter signal stable Why

Overview

When a beam splitter divides the incoming light, some of the energy is inevitably lost, leading to a decrease in signal strength. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. They are used to divide a beam of light into two or more separate beams. Together, they decide just how accurately an instrument captures those unique infrared “fingerprints” from different substances. Beamsplitters are often classified according to their construction: cube or plate. What is the physical phenomenon that occurs in the interaction between a beam of light and a beam splitter that results in two beams of specific proportions of the incoming beam?

2.) How do we know that beam splitters split only the incoming beam and not its constituent photons (I'm assuming that. Plate beam splitters are flat optical components that reflect and transmit incident light, with a 45-degree angle of incidence.
